# Research Faculty Summit 2012

ADVANCING THE STATE OF THE ART

# Touchless Interaction in Surgery

Gerardo Gonzalez  
Senior Research Associate – Lancaster  
University

July 16, 2012

# Project Goal

To allow a surgeon to interact with medical images in the operating room

Medical imaging systems are used to visualize the patient's inner anatomical structure  
The surgeon's interaction with the system is limited due to sterility  
The surgeon needs to depend on someone else to control the system

# Vascular surgery

## Minimally invasive surgery (a.k.a. Keyhole surgery)

Placement of a stent inside the aorta to treat aneurisms

## Medical imaging system components

3D model of the patient's aorta (obtained from a CT scan)

Live fluoroscopic images (updated during the procedure)

## Touchless interaction

Introduce the Kinect for Windows technology

Use of hand gestures to manipulate images

# Touchless Technology in the Operating Room

# Challenges

The operating room is a busy environment

Visual occlusion of the surgeon's lower body

Close proximity of users

Sterile interaction area

Noise environment

Aim to avoid false positives

# Challenges

View from Kinect's perspective in 'idle' mode

# System Interaction

Design of the gesture set in close collaboration with surgeons

Gesture control for 'physical' manipulations

Continuous interaction

One and two hand based interactions

Gestural interaction within 'sterile zone'

Active area of interaction

Voice control for event-driven interaction

Voice commands that surgeons are familiar with

Visual feedback

# System Interaction

First time user

# Future Work

## Touchless interaction for other type of medical procedures

Neurosurgery

Different gesture set

3D volumetric models of the brain

## Toolkit for surgical settings

Development of a gesture framework

# Thank you

## Collaborative work
