# Towards Net-zero homes

Net-zero

# Towards Net-zero homes

Energy budget 2-3x less than grid-only

Question: how do we bridge this gap?

- more energy efficient technology
- usage behavior changes
- apply off-grid usage to grid-tied home

**First Step:** Collect real data

# What are specific challenges in off-grid and grid-tied homes?

Performed online surveys for 8 households

- 4 off-grid, 4 grid-tied (CA, AR, MA, NE, Hawaii)
- wind turbines, solar panels (1.6 KW - 11 KW systems)
- auxiliary power sources such as diesel or propane generators

Need for non-intrusive energy monitoring visualization, control

**“I have a Trimetric readout in the house but it has poor accuracy, it is fairly useless except for incoming and outgoing amps, I would like to be able to access my numbers without trekking up to the power shed and peering at the readout on the outback”**

Several external factors effect energy generation

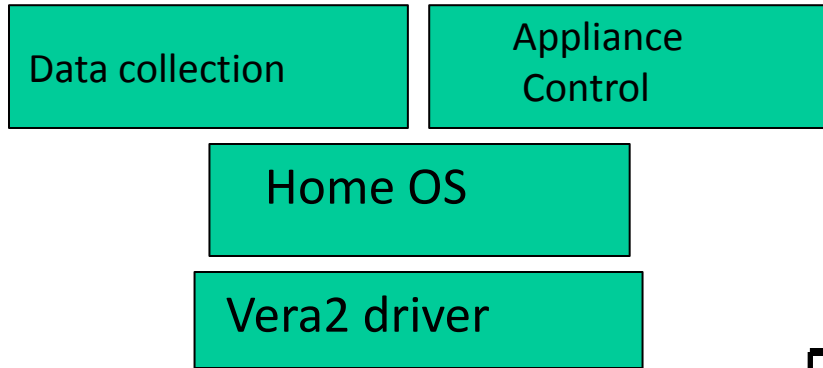

**“mold soots due to oak trees on PV panels” affect power generation as well as “trees surrounding the home”**

Need for automated or semi-automated demand and response systems

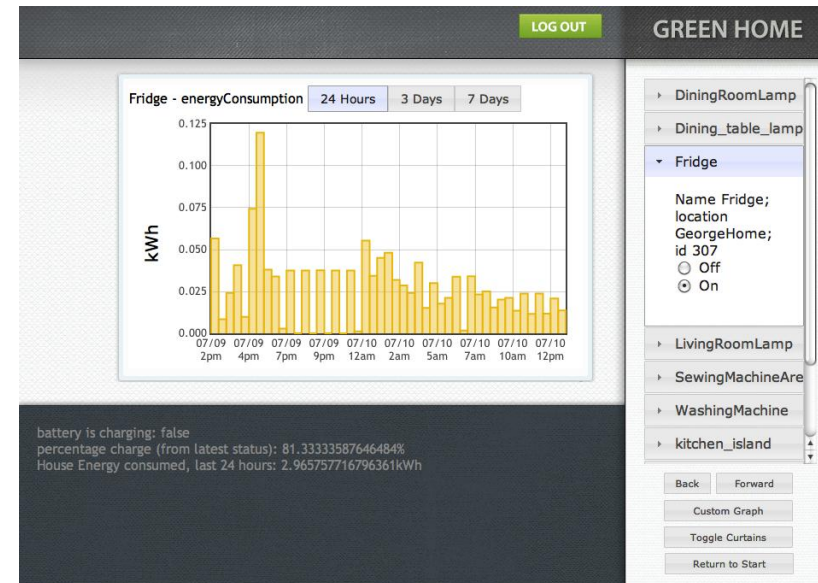

**“I own a vacuum, but only use it on sunny afternoons when the batteries are full, as it is a HUGE energy hog. This means I vacuum a lot less than previously, but find a broom does a decent interim job.”**

# Measurement infrastructure and incentives

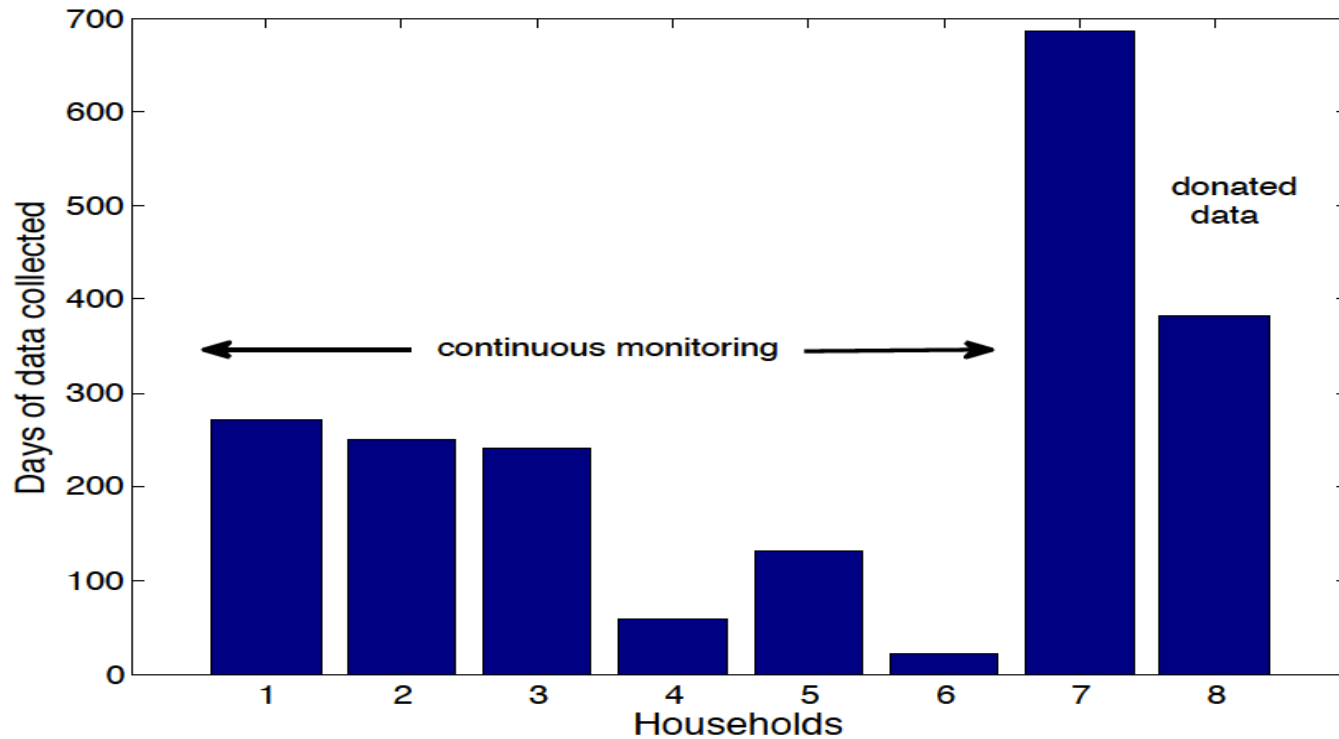

## Home component

## Server component

# Data collected till date

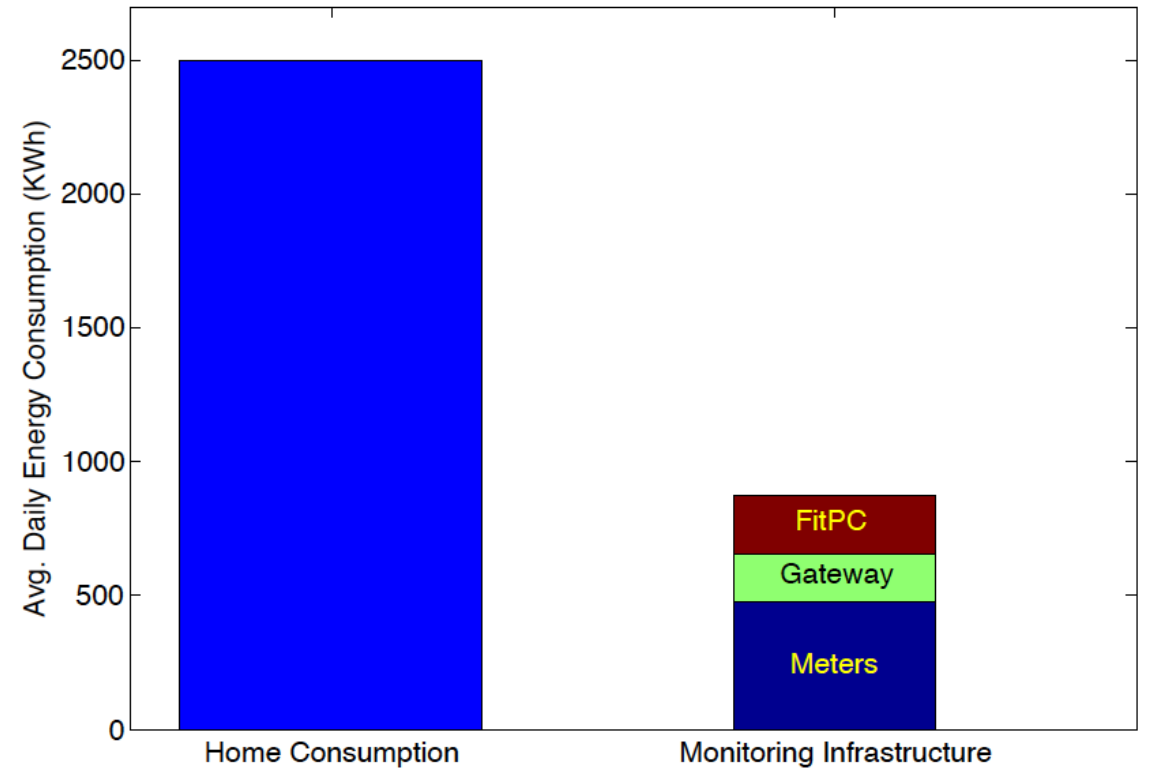

Data from 8 homes (continuous data from 6 homes)

- off-grid and grid-tied (4), grid-only (4) [**> 4 GB of data**]
- **<total home energy, generation, consumption, appliance>**
- 6 more off-grid and grid-tied homes have shown interest

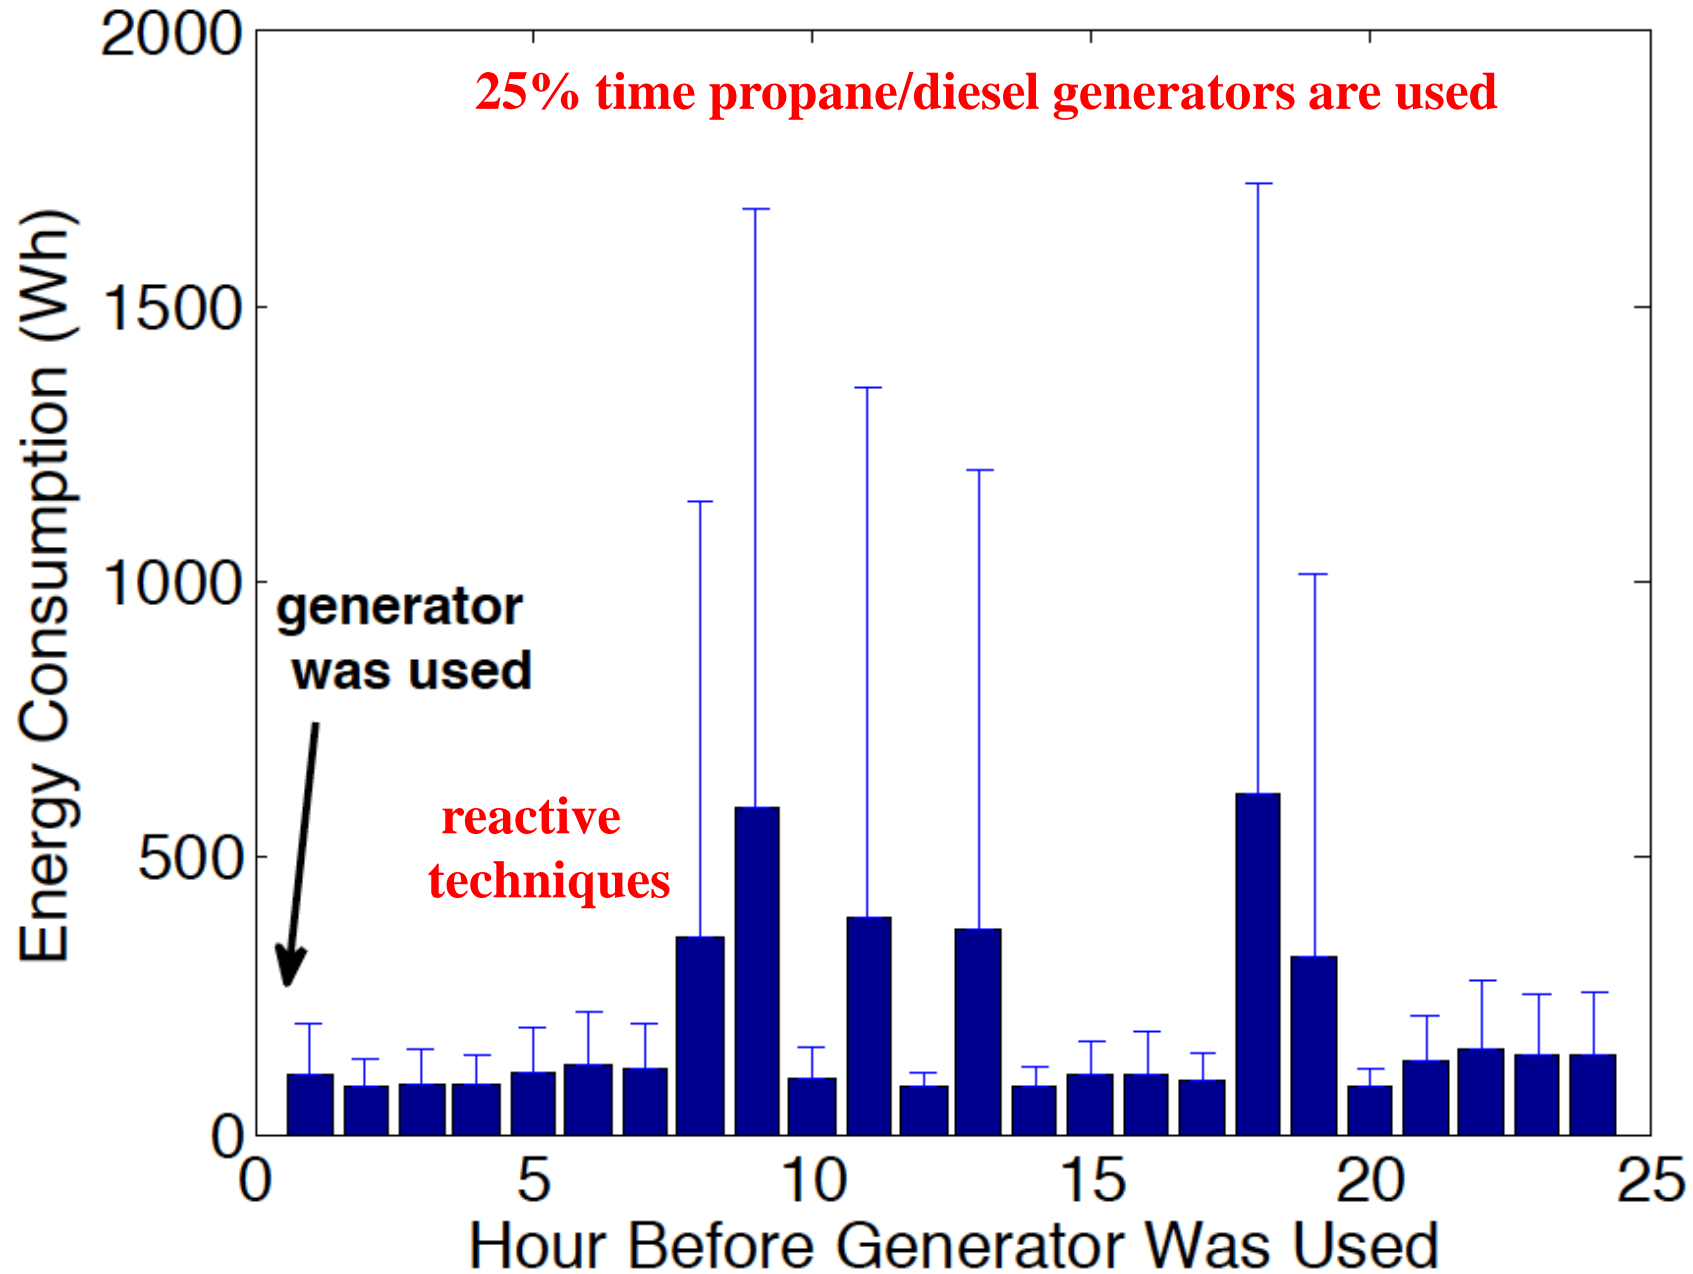

# Non-intrusive energy monitoring

- Sampling Analysis
  - minimize energy/bandwidth overhead
  - capture outliers, energy peaks  
ON times
  - frequency spectrum for time of day
  - Nyquist criterion -> determine  
sampling rate
  - push based approaches, using other context
- Minimal set of appliances to monitor
  - devices that are to be controlled (TV, Lights, PCs) are monitored
  - use unsupervised learning (HMM) and generic profiles
    - determine usage of all appliance from devices monitored
    - recommend additional devices to be monitored

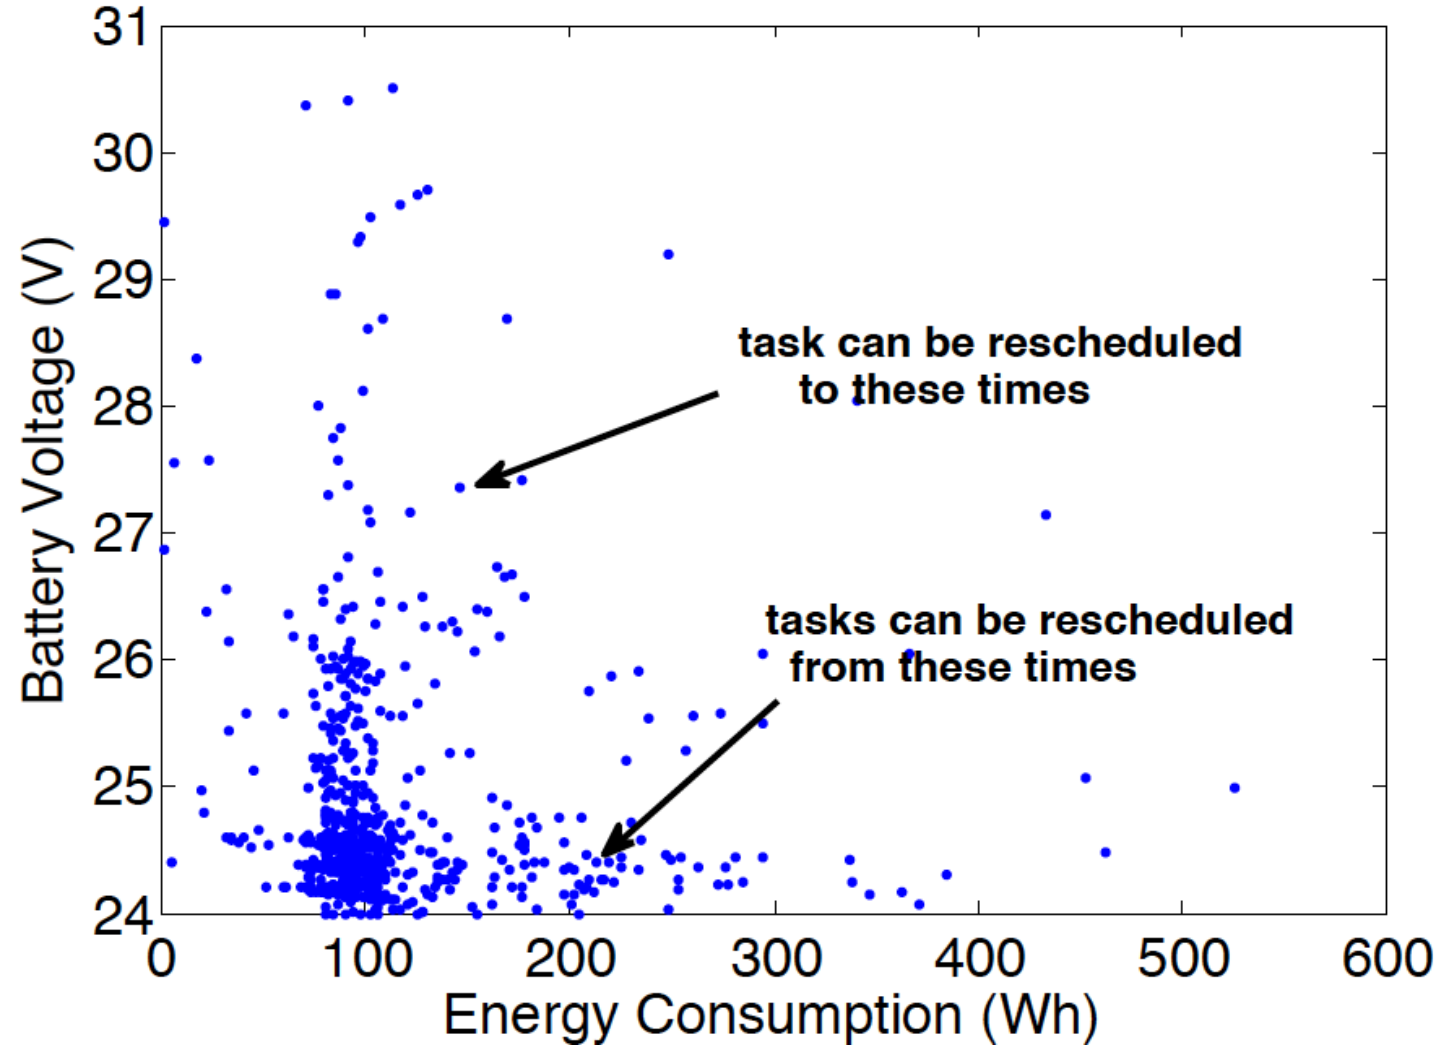

# Insight: off-grid homes are not truly sustainable

# Insight: opportunities for demand response

Energy savings

1500 - 2000 Wh

Equivalent to 2V

24V to 26 V

## Far from conclusion..

- Wider and more robust monitoring infrastructure
  - collect context information through smartphone app, sensors
  - open platform for application development (social networking)
  - home automation for people with disabilities (gesture recognition using wearable nano-structured and fabric sensors)
- Build a recommendation based demand response system
  - off-grid, grid-tied, grid-only
- Understand the differences and similarities in energy consumption in the three types of houses
  - define a energy pathway towards net-zero paradigms
